Exoplanet searches in Radio : Theory & Observations from UTR-2 to LOFAR/SKA

P. Zarka

LESIA, Observatoire de Paris, CNRS, UPMC, Université Paris Diderot, 92190 Meudon, <u>philippe.zarka@obspm.fr</u>

- Jupiter LF radio emission are intense \Rightarrow discovery & measure of B field (~10G) and rotation period (~10h)
- \exists similar Terrestrial emissions, $\leq I$ MHz (B ~ 0.5G)
- Radiation belts emission = synchrotron
- Auroral emissions = Cyclotron-Maser (CMI) : $f=f_{ce}$, keV e-, high T_B, circular polar., narrow beaming, t-f variability
- Contrast Jupiter Sun ~ I \rightarrow radio search !

- Intense sky background (+ RFI + ionosphere) \rightarrow detection difficult
- Maximum distance for N σ sky-limited detection of a source $\zeta \times Jupiter$:

$$d_{max} = (\zeta S_J A_e / 2NkT)^{1/2} (b\tau)^{1/4} = 5 \times 10^{-8} (A_e \zeta)^{1/2} f^{5/4} (b\tau)^{1/4} [pc]$$

	b τ :	= 10 ⁶	b τ = 2×10 ⁸		b τ = 4×10 ¹⁰		
ζ=1	(1 MHz, 1 sec)		(3 MHz, 1 min)		(10 MHz, 1 hour)		
	f = 10	f = 100	f = 10	f = 100	f = 10	f = 100	
	MHz	MHz	MHz	MHz	MHz	MHz	
$A_e = 10^4 \text{ m}^2$	0.003	0.05	0.01	0.2	0.04	0.7	
A _e = 10 ⁵ m ² (~UTR-2, LOFAR)	0.01	0.2	0.03	0.6	0.1	2.2	
A _e = 10 ⁶ m ² (~SKA)	0.03	0.5	0.1	2.	0.4	7.	

(distances in parsecs)

THEORY

- General frame of flow-obstacle interaction in our Solar system : magnetic reconnection, Alfvén waves, Unipolar interaction
- Empirical radio-magnetic scaling law with ~constant efficiency ε~2-10×10⁻³

- → Extrapolation to hot Jupiters :
- Magnetospheric radio emission up to 10⁵ Jupiter
- Unipolar inductor emission up to $\geq 10^{6}$ Jupiter at $\geq 30-300$ MHz, but requires B* $\geq 10-100B$

• Internally driven radio emission of normal Jupiters around highly XUV luminous stars \rightarrow large radio fluxes requires rapid Xo rotation (1-3h)

• Maximum distance for N σ sky-limited detection of a source $\zeta \times \text{Jupiter}$:

	b τ = 10 ⁶		b τ = 2×10 ⁸		b τ = 4×10 ¹⁰		
6 6 5	(1 MHz, 1 sec)		(3 MHz, 1 min)		(10 MHz, 1 hour)		
ζ = 10°	f = 10	f = 100	f = 10	f = 100	f = 10	f = 100	
	MHz	MHz	MHz	MHz	MHz	MHz	
A _e = 10 ⁴ m ² (~NDA))	1	16	3	59	13	220	
A _e = 10 ⁵ m ² (~UTR-2, LOFAR)	3	50	11	190	40	710	
$A_e = 10^6 m^2$ (~SKA)	9	160	3 3	600	130	2200	

(distances in parsecs)

• turbulence \rightarrow intermittency

[Chian et al., 2010]

• scintillations \rightarrow radio flux x 100 ? [Farrell et al., 1999]

- Predicting radio dynamic spectra from CMI modelling for various SPI scenarii
 - no imaging \rightarrow t-f morphology reveals physical parameters
 - successful loss-cone driven CMI modelling of Jupiter's radio emissions :
 - → Meudon ExPRES code

• Star-Exoplanet case : parameters (stellar/exoplanet B tilt/offset, orbit inclination), planetary and stellar rotation, planetary orbital period ...

Orbit inclination Type of interaction

• White dwarf-planet unipolar interaction explains ultrashort period (P<10 min) X-ray sources with antiphase optical emission : X-Ray emission by heated footpoints on magnetic WD + optical emission by irradiation of the companion

- P decrease consistent with power radiation via unipolar induction
- System lifetime due to gravitational radiation emission
- CMI radio emission ?

 \rightarrow may reveal Earth-like planets in close orbit around WD (= remnants of main sequence stars with planet surviving the stellar expansion phase and back in stable orbit)

- Interest of low-frequency radio observations of exoplanets : immense !
 - \rightarrow Direct detection, discovery ?
 - \rightarrow Measurement of B (only way !)

 \Rightarrow contraints on scaling laws & internal structure models

- \rightarrow Planetary rotation period \Rightarrow tidal locking ?
- \rightarrow Possible access to orbit inclination
- → Existence / orbital period of satellites ?
- → Comparative (exo)planetary magnetospheric physics = NEW FIELD, <u>theoretical frame ready, we are leading it</u>

 \rightarrow Magnetosphere favours habitability (limits atmospheric erosion by solar wind & CME, limits destruction of O₃ by cosmic rays)

[Griessmeier et al., 2004; Khodachenko et al., 2006...]

• Synchrotron emission from radiation belts : stable but weak (a few nJy @ I pc)

PREDICTIONS

• Application of scaling laws to exoplanet census \rightarrow target selection

[Lazio et al., 2004]

[Griessmeier et al., 2007, 2011]

• Unipolar inductor CMI radio emission from WD-exoplanet systems

 \rightarrow broadband emission up to 100 GHz (+ absorption bands), 100% circularly polarized bursts (X mode dominant), modulated at the orbital period

- → orbital period modulation : bursts (~10 min), a few % duty-cycle (beaming)
- \rightarrow order of magnitude predictions (N_e of I keV loss-cone e- ×10 \rightarrow S ×10⁴)
- → Limited unipolar inductor lifetime due to spin-orbit coupling

• Stellar B-fields & variable star-planet interaction (SPI)

- Solar B field :
- \rightarrow large-scale ~1 G
- \rightarrow mag. loops ~10³ G
- (few % of surface)
- Magnetic stars : > $10^3 G$
- τ Boo : 5-10 G (10⁻⁴ T)
- HD 76151 : ~10 G
- HD 189733 : >50 G
- HD 171488 : 500G

OBSERVATIONS

• Observations at VLA at 74, 330, 1465 MHz τ Boo, HD 80606 \rightarrow no detection (low A_{eff}, 'HF')

[Winglee et al., 1986; Bastian et al., 2000; Farrell et al., 2003, 2004; Lazio & Farrell, 2007; Lazio et al., 2010]

• Observations at GMRT at 153 MHz

Ups And, ε Eri, HD 128311 \rightarrow no detection

[Winterhalter et al., 2006; Majid et al., 2006; George and Stevens, 2007, 2008]

 τ Boo (> 4M_J, ~0.05 AU, 16 pc, P=79.5h) : 40 h, ~0.4 mJy

\rightarrow no detection

[Hallinan et al., 2013]

 \rightarrow RFI ? B_{planet} < 50G ? (!) emission too weak ?

 Observations at GMRT at 153 MHz, 244, 614 MHz
 → anti-transits of HD189733b, HD209458b
 HAT-P-11b

Time (UT) 

Last minute information : Recent A&A paper by Sirothia et al. Several candidate radio exoplanets in GMRT I 50 MHz survey. To be followed, confirmed, but very encouraging. • Observations at UTR-2, 10-30 MHz dual beam, δ f=4 kHz, δ t=20 msec

[Ryabov et al., 2004, 2010; Zarka et al., in prep]

• Inferred limits (from J. Lazio)

 Observations with LWA, 10-88 MHz 256 antennas, dual beam, mJy sensitivity

[Hallinan et al.]

HJUDE - Hot Jupiter Detection Experiment with the LWA \Rightarrow 5000 hours

Observations with LOFAR,
26-62 MHz, imaging + TAB

[Zarka et al.]

 \rightarrow 5 targets observed 30h in cycle 0

UPS AND, 2013-02-27, 2h, ISB @ 56 MHz : image = 4096x4096 pixels (5") = $6^{\circ} \times 6^{\circ}$ (u,v) \leq 5000 wavelengths, CSclean (CASA)

[Zarka et al.]

 \rightarrow 17 targets to be observed 17h in cycle 1

NEXT ?

LOFAR :

- Search for transients, « naïve approach » : Images (t), Visibilities (t)
- Search for transients : less naïve approach : FT (image pixels),

Compressed Sensing \Rightarrow (2D + t) sparse recovery

• Circular / Full polarization

- 1000's candidates
- Time variability due to narrow beaming / visibility
- Need to observe large sample at low frequencies (< 100 MHz) to overcome geometrical selection effects ⇒ long duty-cycles
- Commensal observations

<u>OLWA</u>

• all sky LWA

NenuFAR :

- In standalone mode, compact array with very high sensitivity
- 10-88 MHz bandwith, 2 full-band beams + 256 pixels maps within a broad FoV (8°-60°)²
- National instrument \Rightarrow possibility of very high duty-cycles

(e.g. Kepler field)

(including observations in // with LOFAR)

• Very high FoM for exoplanet search

Radio Array	Freq. range	Effective	N polar.	% of obs.	Figure of	Field of View	Resolution
	(MHz)	area (m ²)		time	Merit (FoM)	(° ²)	
UTR-2	10-32	~143 000	1	5-10%	157-315	0.25 - 7	30'
(2040 dipoles)							
VLA	73-74.6	~2 000	2	1-5%	<1	68	25"
27 dishes (25 m Ø)							
GMRT	149-157	~30 000	2	1-2%	5-10	5	20"
30 dishes (45 m Ø)							
LOFAR low : 48	30-80	100 000	2	5%	180	10-300	5"-0.9"
stations \times 48/96 dip.		- 14 000			(60)		
LOFAR high : 48 st.	110-250	70 000	2	5%	180	4-30	0.6"-0.3"
× 48/96 × 16 dip.		$-20\ 000$			(60)		
LSS	15-85	47 000	2	20%	384	70-2000	3.8°-0.7°
48 × 19 dipoles		-4 000					

• Possible synergies with complementary instruments : LF radio (UTR-2, GURT, OLWA), ZD spectropolarimetry (cf. above), UV-X * luminosity ...

SKA-LOW

→ Must significantly improve / LOFAR (if no detection)

• Jupiter decameter emission @ 10 pc peaks at ~25 μ Jy (sec - min timescale) / 3 μ Jy (hour timescale), (x20 if planet at ~ 1 AU)

• SKA-low sensitivity: mJy - 10's μ Jy at timescales from sec to hours \rightarrow no more need of scaling laws, ~Jupiter detectable at 10s of pc

• SKA-low baseline design essentially Ok: broad freq. range ≥50 MHz, broad instantaneous coverage, full polar, 50-100 km baselines, radio quiet site (multibeam capability ?)

FAST ?

LOFAR on the Moon ?

• Synergies with white / brown / cool dwarfs & flaring stars studies (cf. above)

- → Brown dwarfs pulses discovered at GHz frequencies
- → Periodic pulses (~2 h), 100% circularly polarized, $T_B > 10^{15}$ K, $|B| \sim 2 kG$

[Osten, Hallinan, et al.]

- from dwarfs to planets (X, H-alpha, T, rotation, transition to stable B geometries)
- lower mass planets more frequent around M dwarfs (habitable?)
- stellar bursts (~type II/III), cause planetary auroras, atmospheric loss
- similar obs. techniques and emission levels (star-planet discrimination via orbital period & polarization)

THIS IS POTENTIALLY A HIGH VISIBILITY HIGH «RETURN» SUBJECT ...
